Java Programming, 9e

Chapter 2

Using Data

Objectives

- Upon completion of this chapter you will be able to:
  - Declare and use constants and variables
  - Use integer data types
  - Use the `boolean` data type
  - Use floating-point data types
  - Use the `char` data type
  - Use the `Scanner` class to accept keyboard input
  - Use the `JOptionPane` class to accept GUI input
  - Perform arithmetic
  - Understand type conversion

CENGAGE

- **Constant**
  - Cannot be changed while program is running

- **Literal constant**
  - Value taken literally at each use

- **Numeric constant**
  - As opposed to a literal constant

- **Unnamed constant**
  - No identifier is associated with it

CENGAGE

- **Variable**
  - A named memory location
  - Used to store a value
  - Can hold only one value at a time
  - Its value can change

- **Data type**
  - A type of data that can be stored
  - How much memory an item occupies
  - What types of operations can be performed on data

Declaring and Using Constants and Variables (3 of 4)

- **Primitive type**
  - A simple data type

- **Reference types**
  - More complex data types

Table 2-1: Java primitive data types	
Keyword	**Description**
byte	Byte-length integer
short	Short integer
int	Integer
long	Long integer
float	Single-precision floating point
double	Double-precision floating point
char	A single character
boolean	A Boolean value (true or false

Declaring Variables (1 of 3)

- Name variables
  - Use naming rules for legal class identifiers

- **Variable declaration**
  - A statement that reserves a named memory location
  - Includes:
    - Data type
    - Identifier
    - Optional assignment operator and assigned value
    - Ending semicolon

CENGAGE

- **Assignment operator**
  - The equal sign (=)
  - The value to the right is assigned to the variable on the left

- **Initialization**
  - An assignment made when declaring a variable

- **Assignment**
  - An assignment made after a variable is declared

- **Associativity**
  - The order in which operands are used with operators

Declaring Variables (3 of 3)

- Declare multiple variables of the same type in separate statements on different lines

```
int myAge = 25;
int yourAge = 19;
```

- When declaring variables of different types, you must use a separate statement for each type

CENGAGE

- A **named constant**:
  - Should not change during program execution
  - Has a data type, name, and value
  - Has a data type preceded by the keyword `final`
  - Can be assigned a value only once
  - Conventionally is given identifiers using all uppercase letters

CENGAGE

Declaring Named Constants (2 of 2)

- Reasons for using named constants:
  - Make programs easier to read and understand
  - Enable you to change a value at one location within a program
  - Reduce typographical errors
  - Stand out as separate from variables
  - Eliminates **magic numbers**

CENGAGE

The Scope of Variables and Constants

- **Scope**
  - The area in which a data item is visible to a program, and in which you can refer to it using its simple identifier

- A variable or constant is in scope from the point it is declared
  - Until the end of the **block of code** where the declaration lies

CENGAGE

- `print()` or `println()` statement
  - Use alone or in combination with a `String`

- **Concatenated**
  - A numeric variable is concatenated to a `String` using the plus sign
  - The entire expression becomes a `String`

- The `println()` method can accept a number or `String`

- Use a dialog box to display values

  `JOptionPane.showMessageDialog()`

  - Does not accept a single numeric variable

- **Null `String`**

  - An empty string: **`""`**

CENGAGE

Concatenating Strings to Variables and Constants (3 of 3)

```java
import javax.swing.JOptionPane;
public class NumbersDialog
{
    public static void main(String[] args)
    {
        int creditDays = 30;
        JOptionPane.showMessageDialog(null, "" + creditDays);
        JOptionPane.showMessageDialog
            (null, "Every bill is due in " + creditDays + " days");
    }
}
```

Figure 2-3 NumbersDialog class

CENGAGE

Pitfall: Forgetting That a Variable Holds One Value at a Time

- Each constant can hold only one value for the duration of the program

- Switch values of two variables
  - Use a third variable

CENGAGE

Learning About Integer Data Types (1 of 2)

- **`int`** data type
  - Stores an **integer**, or whole number
  - Value from −2,147,483,648 to +2,147,483,647

- Variations of the integer type
  - **`byte`**
  - **`short`**
  - **`long`**

- Choose appropriate types for variables

CENGAGE

Learning About Integer Data Types (2 of 2)

Table 2-2: Limits on integer values by type			
Type	**Minimum Value**	**Maximum Value**	**Size in Bytes**
byte	−128	127	1
short	−32,768	32,767	2
int	−2,147,483,648	2,147,483,647	4
long	−9,223,372,036,854,775,808	9,223,372,036,854,775,807	8

Using the `boolean` Data Type (1 of 2)

- Boolean logic
  - Based on true-or-false comparisons

- **`boolean` variable**
  - Can hold only one of two values
  - `true` or `false`

```
boolean isItPayday = false;
```

- **Relational operator** (**comparison operator**)
  - Compares two items

Using the boolean Data Type (2 of 2)

Table 2-3: Relational operators			
Operator	**Description**	**True Example**	**False Example**
<	Less than	3 < 8	8 < 3
>	Greater than	4 > 2	2 > 4
==	Equal to	7 == 7	3 == 9
<=	Less than or equal to	5 <= 5	8 <= 6
>=	Greater than or equal to	7 >= 3	1 >= 2
!=	Not equal to	5 != 6	3 != 3

CENGAGE

- Floating-point number
  - Contains decimal positions

- Floating-point data types
  - float
  - double

- Significant digits
  - Refers to mathematical accuracy

Learning About Floating-Point Data Types (2 of 2)

Table 2-4: Limits on floating-point values			
Type	**Minimum**	**Maximum**	**Size in Bytes**
float	$-3.4 * 10^{38}$	$3.4 * 10^{38}$	4
double	$-1.7 * 10^{308}$	$1.7 * 10^{308}$	8

Using the `char` Data Type (1 of 3)

- **char** data type
  - Holds any single character

- Place constant character values within single quotation marks

  ```
  char myMiddleInitial = 'M';
  ```

- **String**
  - A built-in class
  - Stores and manipulates character strings
  - `String` constants are written between double quotation marks

CENGAGE

- **Escape sequence**
  - Begins with a backslash followed by a character
  - Represents a single nonprinting character

    ```
    char aNewLine = '\n';
    ```

- To produce console output on multiple lines in the command window, use one of these options:
  - Use the newline escape sequence
  - Use the `println()` method multiple times

CENGAGE

Table 2-6: Common escape sequences	
Escape Sequence	**Description**
\b	Backspace; moves the cursor one space to the left
\t	Tab; moves the cursor to the next tab stop
\n	Newline or linefeed; moves the cursor to the beginning of the next line
\r	Carriage return; moves the cursor to the beginning of the current line
\"	Double quotation mark; displays a double quotation mark
\'	Single quotation mark; displays a single quotation mark
\\	Backslash; displays a backslash character

CENGAGE

- `System.in` object
  - **Standard input device**
  - Normally the keyboard
  - Access using the `Scanner` class

- `Scanner` object
  - Breaks input into units called **tokens**

Table 2-7: Selected Scanner class methods	
Method	**Description**
nextDouble()	Retrieves input as a double
nextInt()	Retrieves input as an int
nextLine()	Retrieves the next line of data and returns it as a String
next()	Retrieves the next complete token as a String
nextShort()	Retrieves input as a short
nextByte()	Retrieves input as a byte
nextFloat()	Retrieves input as a float. Note that when you enter an input value that will be stored as a float, you do not type an F. The F is used only with constants coded within a program.
nextLong()	Retrieves input as a long. Note that when you enter an input value that will be stored as a long, you do not type an L. The L is used only with constants coded within a program.

```
import java.util.Scanner;
public class GetUserInfo
{
    public static void main(String[] args)
    {
        String name;
        int age;
        Scanner inputDevice = new Scanner(System.in);
        System.out.print("Please enter your name >> ");
        name = inputDevice.nextLine();
        System.out.print("Please enter your age >> ");
        age = inputDevice.nextInt();
        System.out.println("Your name is " + name +
            " and you are " + age + " years old.");
    }
}
```

The Scanner class is imported, and used to create an object.

The Scanner object is used with the nextLine() method.

Figure 2-17   The GetUserInfo class

Pitfall: Using `nextLine()` Following One of the Other `Scanner` Input Methods

- There is a problem when using one numeric `Scanner` class retrieval method or `next()` method before using the `nextLine()` method

- **Keyboard buffer**
  - Location in memory that stores all keystrokes, including Enter

- To avoid issues, add an extra `nextLine()` method call to retrieve the abandoned Enter key character after numeric or `next()` inputs

CENGAGE

Using the `JOptionPane` Class to Accept GUI Input

- Dialog boxes used to accept user input:
  - Input dialog box
  - Confirm dialog box

CENGAGE

- **Input dialog box**
  - Asks a question
  - Provides a text field in which the user can enter a response

- **showInputDialog() method**
  - Six overloaded versions
  - Returns a `String` representing a user's response

- **Prompt**
  - A message requesting user input

CENGAGE

```java
import javax.swing.JOptionPane;
public class HelloNameDialog
{
   public static void main(String[] args)
   {
      String result;
      result = JOptionPane.showInputDialog(null, "What is your name?");
      JOptionPane.showMessageDialog(null, "Hello, " + result + "!");
   }
}
```

Figure 2-26   The HelloNameDialog class

Figure 2-27   Input dialog box of the `HelloNameDialog` application

- `showInputDialog()`
  - One version requires four arguments:
    - Parent component
    - Message
    - Title
    - Type of dialog box

- **Convert** `String` **to** `int` **or** `double`
  - Use methods from the built-in Java classes `Integer` **and** `Double`

CENGAGE

- **Type-wrapper classes**
  - Each primitive type has a corresponding class contained in the `java.lang` package
  - Include methods to process primitive type values
    ```
    Integer.parseInt()
    Double.parseDouble()
    ```

- **Confirm dialog box**
  - Displays the options Yes, No, and Cancel

- **`showConfirmDialog()` method** in `JOptionPane` class
  - Four overloaded versions are available
  - Returns integer containing either:

```
JOptionPane.YES_OPTION
JOptionPane.NO_OPTION
JOptionPane.CANCEL_OPTION
```

CENGAGE

- You can create a confirm dialog box with five arguments:
  - Parent component
  - Prompt message
  - Title
  - Integer that indicates which option button to show
 - Integer that describes the kind of dialog box

Figure 2-33 The confirm dialog box displayed by the AirlineDialog application

Performing Arithmetic Using Variables and Constants (1 of 2)

- **Standard arithmetic operators**
  - Perform calculations with values in programs

- **Operand**
  - A value used on either side of an operator

- **Integer division**
  - Involves integer constants or integer variables
  - The result is an integer
  - Any fractional part of the result is lost

CENGAGE

Table 2-8: Arithmetic operators		
Operator	Description	Example
+	Addition	45 + 2, the result is 47
−	Subtraction	45 − 2, the result is 43
*	Multiplication	45 * 2, the result is 90
/	Division	45.0 / 2, the result is 22.5 45 / 2, the result is 22 (not 22.5)
%	Remainder (modulus)	45 % 2, the result is 1 (that is, 45/2 = 22 with a remainder of 1)

CENGAGE

Associativity and Precedence

- **Operator precedence**
  - The rules for the order in which parts of mathematical expressions are evaluated
  - First multiplication, division, and remainder (modulus), then addition or subtraction

Writing Arithmetic Statements Efficiently

- Avoid unnecessary repetition of arithmetic statements

- Example of inefficient calculation:

```
stateWithholding = hours * rate * STATE_RATE;
federalWithholding = hours * rate * FED_RATE;
```

- Example of efficient calculation:

```
grossPay = hours * rate;
stateWithholding = grossPay * STATE_RATE;
federalWithholding = grossPay * FED_RATE;
```

CENGAGE

Pitfall: Not Understanding Imprecision in Floating-Point Numbers

- Integer values are exact
  - But floating-point numbers frequently are only approximations

- Imprecision leads to several problems
  - Floating-point output might not look like what you expect or want
  - Comparisons with floating-point numbers might not be what you expect or want

CENGAGE

Understanding Type Conversion

- Arithmetic with variables or constants of the same type
  - The result of arithmetic retains the same type

- Arithmetic operations with operands of unlike types
  - Java chooses the unifying type for the result

- **Unifying type**
  - The type to which all operands in an expression are converted for compatibility

CENGAGE

Automatic Type Conversion

- Automatically converts nonconforming operands to the unifying type

- Order for establishing unifying types between two variables (highest to lowest):
  1. `double`
  2. `float`
  3. `long`
  4. `int`

CENGAGE

Explicit Type Conversions

- **Type casting**
  - Forces a value of one data type to be used as a value of another data type

- **Cast operator**
  - Place desired result type in parentheses
  - Using a cast operator is an **explicit conversion**

- You do not need to perform a cast when assigning a value to a higher unifying type

CENGAGE

Don't Do It (1 of 2)

- Don't mispronounce *integer*

- Don't attempt to assign a literal constant floating-point number

- Don't forget precedence rules

- Don't forget that integer division results in an integer

- Don't attempt to assign a constant decimal value to an integer using a leading 0

- Don't use a single equal sign (=) in a Boolean comparison for equality

- Don't try to store a string of characters in a `char` variable

Don't Do It (2 of 2)

- Don't forget that when a `String` and a numeric value are concatenated, the resulting expression is a string

- Don't forget to consume the Enter key after numeric input using the `Scanner` class when a `nextLine()` method call follows

- Don't forget to use the appropriate import statement when using the `Scanner` or `JOptionPane` class

- Don't forget precedence rules

- Don't forget that integer division results in an integer

- Don't forget that floating—point numbers are imprecise

- Don't use a single equal sign in a Boolean for comparison for equality

CENGAGE

- Variables
  - Named memory locations

- Primitive data types

- Standard arithmetic operators for integers:

  `+, _, *, /,` and `%`

- Boolean type
  - `true` or `false` value

- Relational operators:

  `>, <, ==, >=, <=,` and `!=`

- Floating-point data types
  - `float`
  - `double`
- `char` data type
- `Scanner` class
  - Access keyboard input
- `JOptionPane`
  - Confirm dialog box
  - Input dialog box
